

NewEra Multi-Factor Edit (MFE)

- An example of a practical ZTA implementation step
- ZTA says access rules must be as granular as possible
- Traditional PERMITs at dataset level
 - No member-level granularity in RACF
 - PARMLIBs and PROCLIBs – all or nothing access
- MFE provides member and UNIX file “categories”
- Restricts categories of a configuration to specific USERIDs
- Enhanced access control by category
 - MFA, one-time-use tokens, etc.

Integrity Controls Environment (ICE)

[A New Tool to Enhance z/OS Configuration Security by helping you create a ZTA!](#)

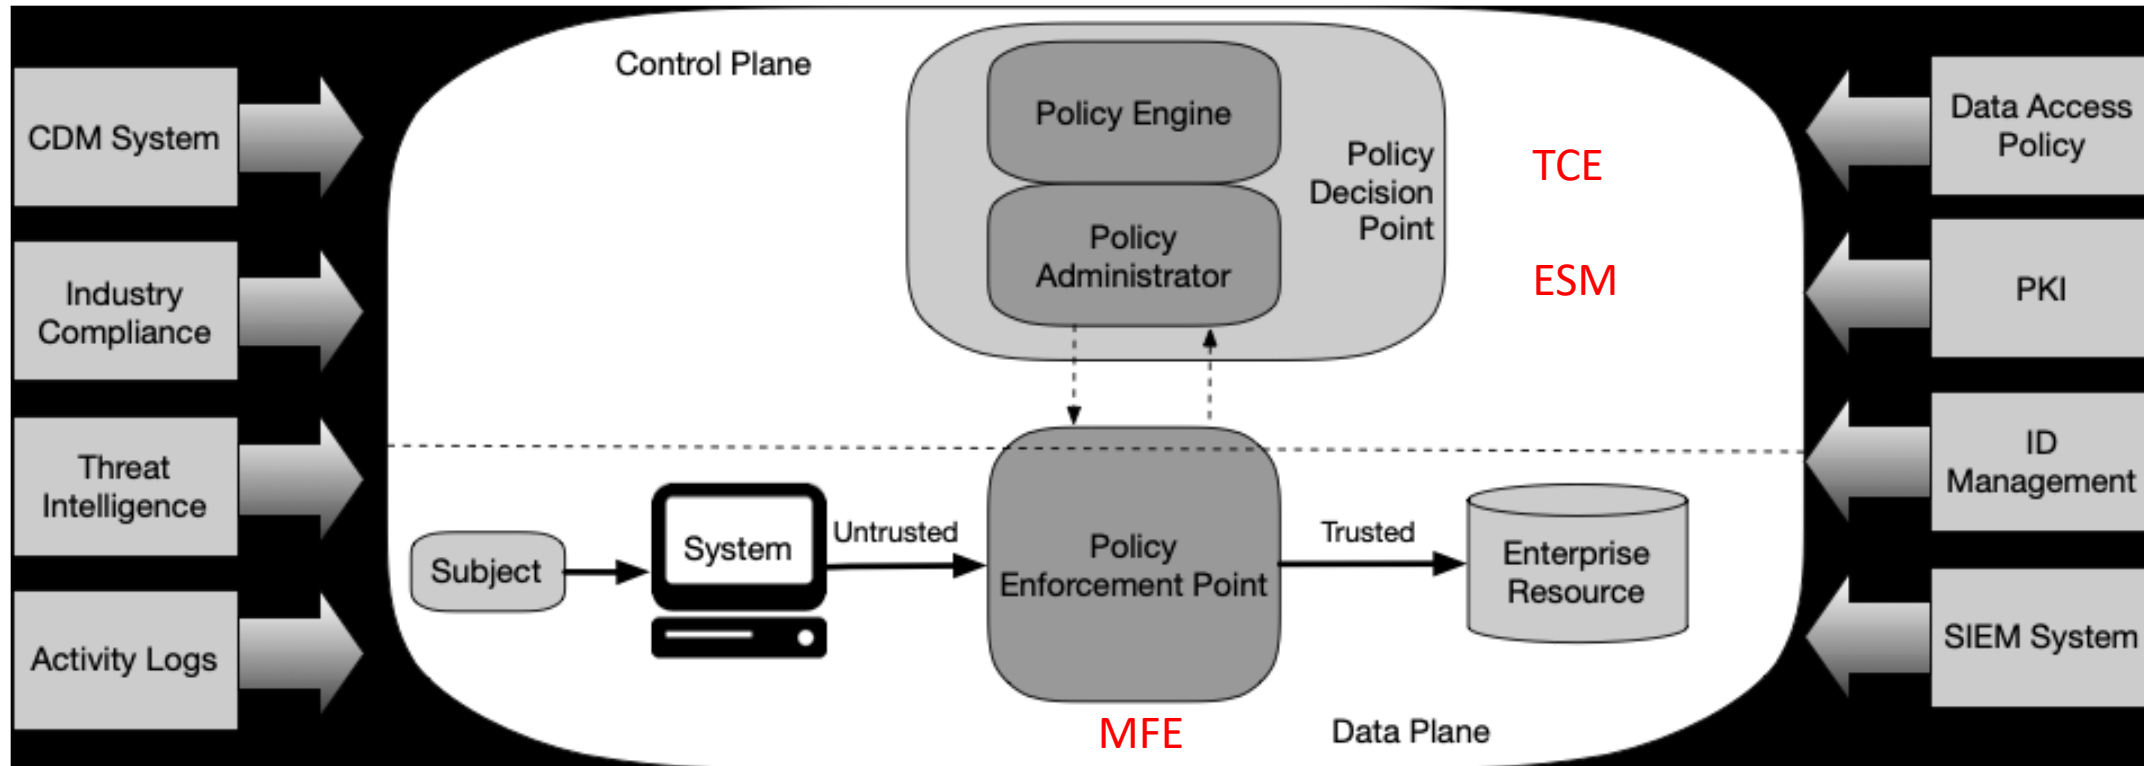

Multi-Factor Edit (MFE) is an extension of the available ICE control structures that surround a TCE Category. In practice it requires that a category be defined as an MFE Controlled Profile. Once a Profile is defined all access to its Datasets, Files and/or Load Libraries will be Denied/Warned unless/until users are specifically permitted access to the Profile.

Permitted users attempting access will receive, or their designate will receive, a One-Time Pass Ticket by Email/SMS. This event specific OTP must be entered by the requesting user in order to continue along the access/update path. All actions taken by the user while in a TCE Controlled TSO/ISPF Edit Space immediately invoke TCE Descriptor and Journaling.

In this introductory webcast, we will describe how MFE uniquely ensures full transparency and full disclosure of resource access/update to events and, in doing so, enhances/supplements the security boundaries you already have in place as provided by either or all of the External Security Managers. No changes to existing, in place security controls are required as MFE is an enhancement to and not a replacement that fully supports the security provided by RACF, ACF2 or Top Secret.

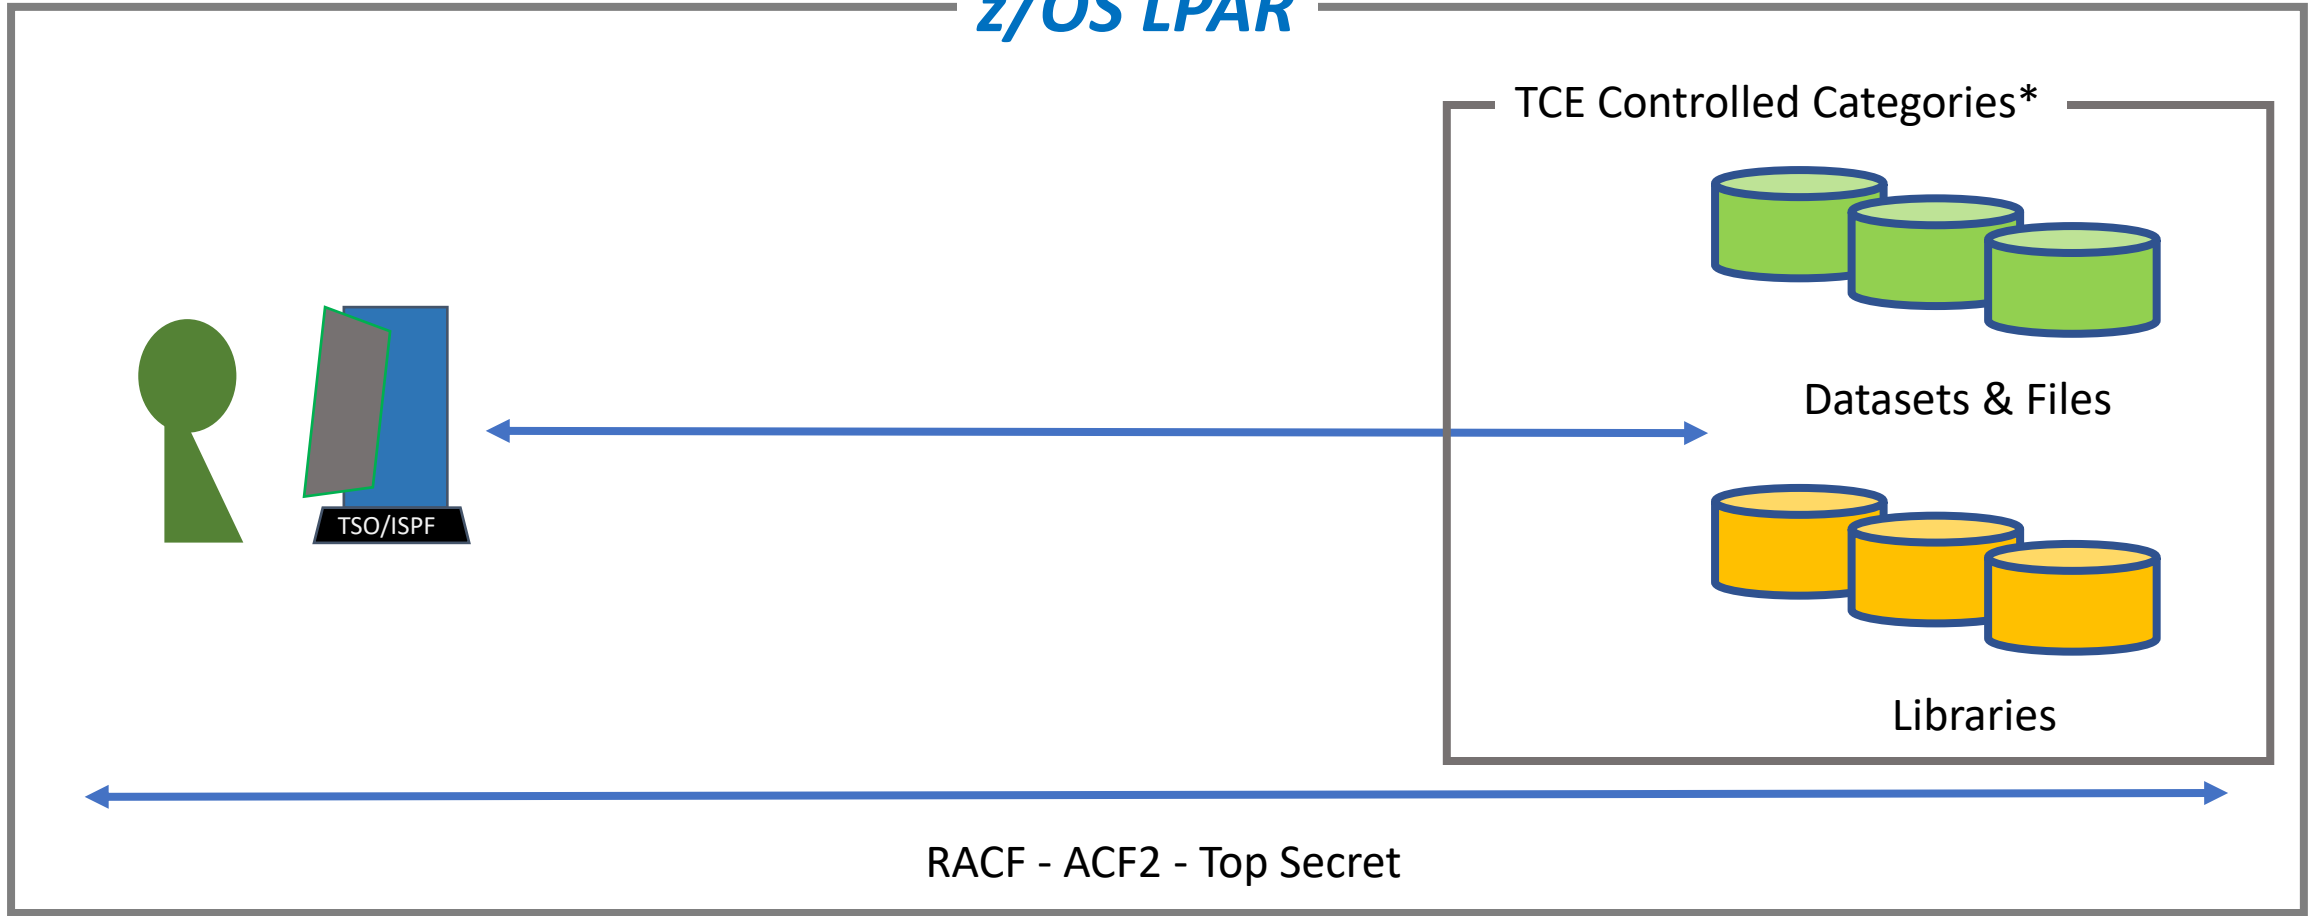

Logical Components of ZTA
